

Visual Language Comparison - Technical vs Business Context

This repository includes a comparison of the same dashboard graph presented in two different visual languages. The purpose of this comparison is not aesthetic - it is to show how the same underlying operational logic can be expressed differently depending on context in different visual languages.

Technical Visual Language

A stripped-back version used in the GitHub repository. It removes stylistic elements, so the focus remains on:

- the validation logic
- the correction cycle
- the measurable improvement in data reliability

This version is intentionally minimal to make the process visible without distraction.

Business Visual Language

A version aligned with the visual standards of the organisation I analyse for. It reflects how the same information is communicated in environments where:

- brand consistency
- presentation clarity
- and stakeholder readability

are required.

Despite the difference in appearance, **both visuals represent the same outcome**: a significant improvement in data reliability after the recount and validation cycle.

Purpose of the System

The **FMCG Demand Planning & Data Validation System** was built as an operational framework robust enough to transform raw, inconsistent FMCG data into a format that can be trusted for demand planning.

The system:

- validates data before use
- identifies inconsistencies
- introduces a recount and correction loop
- applies adjustments without overwriting original data
- recalculates planning outputs
- re-evaluates reliability after intervention

This reduces the operational risks associated with:

- over-stocks
- short-stocks
- cash-flow volatility

The visuals included in this repository simply illustrate the measurable improvement in reliability after the correction cycle.

Key Principle

Reliable decisions do not require perfect data - they require systems that can identify what can be trusted.
